File systems:

- Unix is a tree-like file system
- slash (/) = root
- 2 entities: files & directories (each have operations for: creating, modifying and deleting) --> use recursive operations for its children (not always)
- multiuser system: human and processes systems, organised in groups
  - user root = first and most powerful user
- rights for users and groups, for each file and directory
- special folders (/home, /var, /etc ...)

GCC compiler:

- to compile a C/C++ source:
  - gcc -o <executable to be created> <source-code-file.c>
  - ex: **gcc -o hello hello.c**
    - to run it: **./hello**
- to see the compilations warnings: **gcc -o *name* -Wall**
- echo $PATH = prints the path environment variable -- to launch an executable:
  - ./name = search and launch the executable name in the current folder
  - name = search and launch the exe in $PATH in order
- getopt = iterates arguments passed on the command line
